

Communication through wireless channel

- Fading
- Diversity: temporal, spatial, frequency

Tarokh et al (1998, 1999): space-time coding

- Concentrate on block codes
- Quasistatic fading (block fading)
- Perfect channel information at receiver

## Model parameters

- $n$ : # Tx antennae.
- $m$ : # Rx antennae
- $\alpha_{i,j}$ : path gain from Tx  $i$  to Rx  $j$   
Assume  $\alpha_{i,j}$ 's are IID  $\sim \mathcal{N}(0, 1/2 \text{ per dim})$ .
- $l$ : block length
- $c_t^i$ : Tx signal at time  $t$  by Tx antenna  $i$
- $r_t^j$ : Rx signal at time  $t$  by Rx antenna  $j$
- $\eta_t^j$ : AWGN  $\sim \mathcal{N}(0, 1/SNR \text{ per dim})$

Model (cont.)

- Codeword  $\mathbf{c} = (c_1^1, \dots, c_l^1, c_1^2, \dots, c_l^2, \dots, c_1^n, \dots, c_l^n)$
- Receiver obtains

$$r_t^j = \sum_{i=1}^n \alpha_{i,j} c_t^i + \eta_t^j$$

Optimal decision: choose  $\mathbf{c}$  that minimizes

$$\sum_{t=1}^l \sum_{j=1}^m \left| r_t^j - \sum_{i=1}^n \alpha_{i,j} c_t^i \right|^2$$

Derivation of performance criteria

- Using  $\mathcal{Q}(x) \leq \exp(-x^2/2)$ ,

$$P(\mathbf{c} \rightarrow \mathbf{e} | \alpha_{i,j}) \leq \exp \left[ -\frac{SNR}{2} d^2(\mathbf{c}, \mathbf{e}) \right], \text{ where}$$

$$d^2(\mathbf{c}, \mathbf{e}) = \sum_{j=1}^m \sum_{t=1}^l \left| \sum_{i=1}^n \alpha_{i,j} c_t^i - \sum_{i=1}^n \alpha_{i,j} e_t^i \right|^2$$

- $\Omega_j \cong (\alpha_{i,j}, \dots, \alpha_{n,j})$ ,

$$A_{i,i'} \cong (c_1^i - e_1^i, \dots, c_l^i - e_l^i) \cdot (c_1^{i'} - e_1^{i'}, \dots, c_l^{i'} - e_l^{i'})$$

$$\Rightarrow d^2(\mathbf{c}, \mathbf{e}) = \sum_{j=1}^m \Omega_j A \Omega_j^*$$

$$P(\mathbf{c} \rightarrow \mathbf{e} | \alpha_{i,j}) \leq \exp \left[ -\frac{SNR}{2} \sum_{j=1}^m \Omega_j A \Omega_j^* \right]$$

Derivation of performance criteria (cont.)

$$P(\mathbf{c} \rightarrow \mathbf{e} | \alpha_{i,j}) \leq \exp \left[ -\frac{SNR}{2} \sum_{j=1}^m \Omega_j A \Omega_j^* \right]$$

- $\lambda_1, \dots, \lambda_n \cong$  eigenvalues of  $A$  (possibly 0)

$A$  is Hermitian  $\Rightarrow \lambda_i$ 's are real and nonnegative

$r \cong$  rank of  $A$

- By averaging over  $\alpha_{i,j}$ 's and with some algebra,

$$P(\mathbf{c} \rightarrow \mathbf{e}) \leq \left( \prod_{i=1}^r \lambda_i \right)^{-m} \left( \frac{SNR}{2} \right)^{-rm}$$

$rm$ : diversity advantage (diversity order)

$(\prod_{i=1}^r \lambda_i)^{1/r}$ : coding advantage

- Concentrate on diversity order (why?)

Derivation of performance criteria (cont.)

$$B(\mathbf{c}, \mathbf{e}) \cong \begin{bmatrix} e_1^1 - c_1^1 & e_2^1 - c_2^1 & \cdots & e_l^1 - c_l^1 \\ e_1^2 - c_1^2 & e_2^2 - c_2^2 & \cdots & e_l^2 - c_l^2 \\ \vdots & \vdots & & \vdots \\ e_1^n - c_1^n & e_2^n - c_2^n & \cdots & e_l^n - c_l^n \end{bmatrix}$$

- $B(\mathbf{c}, \mathbf{e})$  is a square root matrix of  $A(\mathbf{c}, \mathbf{e})$ , i.e.  $A = BB^*$   
 $\text{rank}(B) = \text{rank}(A)$
- The rank criterion:

For maximum diversity order  $nm$ ,

make  $B(\mathbf{c}, \mathbf{e})$  full rank for all  $(\mathbf{c}, \mathbf{e})$  pairs.

## Real orthogonal designs

**Definition:** A real orthogonal design of size  $n$  is an  $n \times n$  orthogonal matrix whose rows are permutations of real numbers  $\pm x_1, \dots, \pm x_n$ .

e.g. 
$$\begin{bmatrix} x_1 & x_2 \\ -x_2 & x_1 \end{bmatrix}, \quad \begin{bmatrix} x_1 & x_2 & x_3 & x_4 \\ -x_2 & x_1 & -x_4 & x_3 \\ -x_3 & x_4 & x_1 & -x_2 \\ -x_4 & -x_3 & x_2 & x_1 \end{bmatrix}$$

- WLG, 1st row is  $(x_1, \dots, x_n)$ .
- Hurwitz-Radon theory: real orthogonal designs exist if and only if  $n = 2, 4$ , or  $8$ .

## Space-time block codes from real orthogonal designs

- $\mathcal{A}$ : real constellation of size  $2^b$

**Theorem:** If diversity order is  $nm$ , Tx rate  $\leq b$  bits/s/Hz.

- Encoder takes in blocks of  $nb$  bits.

Encoder picks  $s_i, 1 \leq i \leq n$ , from  $\mathcal{A}$ .

Build an orthogonal design  $\mathcal{O}(s_1, \dots, s_n)$ .

At time  $t$ ,  $n$  antennae transmit  $t^{\text{th}}$  row of  $\mathcal{O}$ .

- Tx rate is  $b$  bits/s/Hz.

**Theorem:** The diversity order of code from orthogonal design

$\mathcal{O}$  is  $nm$ .

- But only good for  $n = 2, 4$ , or  $8$ .

## Generalized real orthogonal designs

**Definition:** A generalized real orthogonal design of size  $n$  is an  $p \times n$  matrix  $\mathcal{G}$  with entries  $0, \pm x_1, \dots, \pm x_k$  such that

$\mathcal{G}^* \mathcal{G} = D$ , a  $p \times p$  diagonal matrix whose  $i^{\text{th}}$  diagonal entry is of the form  $l_1^i x_1^2 + \dots + l_k^i x_k^2$  with  $l_1^i = \dots = l_k^i$  being strictly positive integers.

WLG,  $\mathcal{G}^* \mathcal{G} = I(x_1^2 + \dots + x_k^2)$  ( $p \times p$  matrix).

$$e.g. \quad \mathcal{G}_3 = \begin{bmatrix} x_1 & x_2 & x_3 \\ -x_2 & x_1 & -x_4 \\ -x_3 & x_4 & x_1 \\ -x_4 & x_3 & x_2 \end{bmatrix}, \quad \mathcal{G}_5 = \begin{bmatrix} x_1 & x_2 & x_3 & x_4 & x_5 \\ -x_2 & x_1 & x_4 & -x_3 & x_6 \\ -x_3 & -x_4 & x_1 & x_2 & x_7 \\ -x_4 & x_3 & -x_2 & x_1 & x_8 \\ -x_5 & -x_6 & -x_7 & -x_8 & x_1 \\ -x_6 & x_5 & -x_8 & x_7 & -x_2 \\ -x_7 & x_8 & x_5 & -x_6 & -x_3 \\ -x_8 & -x_7 & x_6 & x_5 & -x_4 \end{bmatrix}.$$

## Space-time block codes from generalized real orthogonal designs

- $\mathcal{A}$ : real constellation of size  $2^b$
- Encoder takes in blocks of  $kb$  bits.

Encoder picks  $s_i, 1 \leq i \leq k$ , from  $\mathcal{A}$ .

Build an orthogonal design  $\mathcal{G}(s_1, \dots, s_k)$ .

At time  $t$ ,  $n$  antennae transmit  $t^{\text{th}}$  row of  $\mathcal{G}$ .

- Tx rate is  $kb \leq pb$  bits/s/Hz.

The rate of the code is  $k/p$ .

**Theorem:** The diversity order of code from orthogonal design  $\mathcal{G}$  is  $nm$ .

- But is it good for all  $n$ ?

Fundamental question of generalized orthogonal design theory

- $A(R, n) \cong \min p$  such that a  $p \times n$  generalized orthogonal design with rate  $\geq R$  exists.

If no such  $p$  exists, let  $A(R, n) = \infty$ .

- Finding  $A(R, n)$  is the fundamental question.

Most interesting  $A(1, n)$  for efficiency.

**Theorem:**  $A(R, n) < \infty$  for any  $R$ .

Construction of  $\mathcal{G}(x_1, \dots, x_p)$  with rate 1

- Hurwitz-Radon family of matrices

**Definition:** A set of  $n \times n$  real matrices  $\{B_1, \dots, B_k\}$  is called a size  $k$  Hurwitz-Radon family of matrices if

$$\begin{aligned} B_i^* B_i &= I, \quad B_i^* = -B_i, \quad 1 \leq i \leq k, \\ B_i B_j &= -B_j B_i, \quad 1 \leq i, j \leq k. \end{aligned}$$

- Hurwitz-Radon theory: any Hurwitz-Radon family of matrices contains less than  $\rho(n) \leq n$  matrices.

Write  $n = 2^a b$ ,  $b$  odd,  $a = 4c + d$  with  $0 \leq d < 4$ ,  $0 \leq c$ .

$$\rho(n) = 8c + 2^d \leq n$$

For any  $n$ , by explicit construction, there exists a Hurwitz-Radon family with  $\rho(n) - 1$  integer matrices (all entries are 0 or  $\pm 1$ ).

Construction of  $\mathcal{G}(x_1, \dots, x_p)$  with rate 1 (cont.)

- Choose a Hurwitz-Radon family of  $\rho(p) - 1$  integer matrices  $\{A_1, A_2, \dots, A_{\rho(p)-1}\}$ .

$$A_0 \cong I, X \cong (x_1, \dots, x_p)$$

- Construct a  $p \times n$  matrix  $\mathcal{G}(x_1, \dots, x_p)$  by setting the  $j^{\text{th}}$  column of  $\mathcal{G}$  to  $A_{j-1}X^*$ .

- $\mathcal{G}$  of size  $n$  exists for all  $n$ .

Can construct space-time block codes for all  $n$ .

But the block length  $p$  can be large?

(Orthogonal designs are delay optimal at  $n = 2, 4$ , and  $8$ .)

## Complex orthogonal designs

**Definition:** A complex orthogonal design  $\mathcal{O}_c$  of size  $n$  is an orthogonal matrix whose rows are permutations of  $\pm x_1, \dots, \pm x_n$ , their conjugates  $\pm x_1^*, \dots, \pm x_n^*$ , or multiples of these indeterminates by  $\pm\sqrt{-1}$ .

- Complex orthogonal designs exist if and only if  $n = 2$ .
- Generalized complex orthogonal designs are similarly defined.

Designs are known to exist for any  $n$  only for rate  $R \leq 1/2$ .

For rate  $R > 1/2$ , block codes of rate  $3/4$  for  $n = 3$  and  $4$  are shown to exist by explicit construction.

Designs with rate  $R > 1/2$  are still not well understood.

## Summary

- Model: block fading, IID path gains, perfect channel info
- Rank criterion for space-time coding
- Real orthogonal designs:  $n = 2, 4$ , or  $8$
- Generalized real orthogonal designs
- Block codes from orthogonal designs: rate 1 for any  $n$
- Complex orthogonal designs: rate  $\leq 1/2$  for any  $n$

**Theorem:** If diversity order is  $nm$  and  $|\mathcal{A}| = 2^b$ , Tx rate  $\leq b$  bits/s/Hz.

**Proof:** View each code word  $\mathbf{c}$  as a member in  $[\mathcal{A}^l]^n$ .

$$c_1^1 \cdots c_1^n c_2^1 \cdots c_2^n \cdots c_l^1 \cdots c_l^n = [(c_1^1 \cdots c_l^1), \cdots, (c_1^n \cdots c_l^n)]$$

$A_{2^{bl}}(n, r) \cong$  max size of code with block length  $l$  and Hamming distance  $r$  over constellation size  $2^{bl}$ .

Since  $B(\mathbf{c}, \mathbf{e})$  has rank at least  $r$ , at least  $r$  rows are nonzero.

Thus, the Hamming distance is at least  $r$  for all codewords in  $[\mathcal{A}^l]^n$ .

$$\text{Tx rate} \leq \frac{\log_2 A_{2^{bl}}(n, r)}{l}.$$

For  $r = n$ ,  $A_{2^{bl}}(n, n) = 2^{bl}$  (repetition code). □

**Theorem:** Diversity order of code from orthogonal design  $\mathcal{O}$  is  $nm$ .

**Proof:** The rank criterion requires nonsingularity of

$$B(\tilde{\mathbf{s}}, \mathbf{s}) = \mathcal{O}(\tilde{s}_1, \dots, \tilde{s}_n) - \mathcal{O}(s_1, \dots, s_n).$$

Note that

$$\mathcal{O}(\tilde{s}_1, \dots, \tilde{s}_n) - \mathcal{O}(s_1, \dots, s_n) = \mathcal{O}(\tilde{s}_1 - s_1, \dots, \tilde{s}_n - s_n),$$

and

$$\det(\mathcal{O}) = \det(\mathcal{O}\mathcal{O}^*)^{1/2} = \left[ \sum_i x_i^2 \right]^{n/2}.$$

Thus

$$\det(\mathcal{O}(\tilde{s}_1 - s_1, \dots, \tilde{s}_n - s_n)) = \left[ \sum_i |\tilde{s}_i - s_i|^2 \right]^{n/2} > 0.$$
