Goals

- Introduce non-equilibrium statistical physics and its recent applications to Active Matter.
- Give you the tools you will need to model and study non-equilibrium systems
- Introduce important examples and hot topics

Organization of lectures

Part I: Relaxations towards equilibrium (Lectures 1-5)

- Dynamics of a colloid in a bath
(Construction of Langevin equation)
- Stochastic Itô calculus (Derivation of the Fokker-Planck equation)
- Currents and time-reversal symmetry

Part II: Non-equilibrium & active dynamics (Lectures 6-13)

- Ratchets: from Feynman to molecular motors
- Active particles: bacteria and self-propelled colloids
- Collective behaviours in active systems: phase separation and collective motion
